

primary studies - published RCT

Short-term effects of positive expiratory pressure mask on ventilation inhomogeneity in children with cystic fibrosis: A randomized, sham-controlled crossover study.

Code: PM38362833

Year: 2024 Date:

Author: Gambazza S

Study design (if review, criteria of inclusion for studies)

Randomized, sham-controlled crossover trial

Participants

Children with cystic fibrosis

Interventions

Positive expiratory pressure (PEP) mask.

Outcome measures

Authors used the nitrogen multiple-breath washout (N(2) MBW) test to measure diffusion-convection-dependent inhomogeneity arising within the intracinar compartment ($S(\text{acin}) \cdot VT$). Two N(2) MBW tests were performed near the hospital discharge date: one before and the other after PEP mask therapy (1 min of breathing through a flow-dependent PEP device attached to a face mask, followed by three huffs and one cough repeated 10 times) by either a standard (10-15 cmH₂O) or a sham (

Main results

The study sample was 19 cwCF (ten girls), aged 11.4 (2.7) years. The adjusted $S(\text{acin}) \cdot VT$ mean difference between the standard and the sham procedure was -0.015 (90% confidence interval [CI]: -0.025 to 0.025) L(-1). There was no statistically significant difference in $S(\text{cond}) \cdot VT$ and lung clearance index between the two procedures: -0.005 (95% CI: -0.019 to 0.01) L(-1) and 0.49 (95% CI: -0.05 to 1.03) turnovers, respectively.

Authors' conclusions

Findings do not support evidence for an immediate effect of PEP mask physiotherapy on $S(\text{acin}) \cdot VT$ with pressure range 10-15 cmH₂O. Measurement with the N(2) MBW and the crossover design were found to be time-consuming and unsuitable for a short-term study of airway clearance techniques.
