Pneumococcal vaccines for cystic fibrosis

Code: CD008865

Year: 2016 **Date:** 2012 - updated: 27 JUN 2016

Author: Burgess Laura

Study design (if review, criteria of inclusion for studies)

Randomised and quasi-randomised controlled trials comparing pneumococcal vaccination (with either a polysaccharide or conjugate pneumococcal vaccine) with non-vaccination or placebo in children or adults with cystic fibrosis were eligible for inclusion

Participants

Children and adults with cystic fibrosis.

Interventions

Pneumococcal vaccination (with either a polysaccharide or conjugate pneumococcal vaccine) vs non-vaccination or placebo

Outcome measures

Primary outcomes: QoL, pulmonary exacerbation, need for hospitalisation, need for additional antibiotic therapy (oral, intravenous), infection with pneumococcus (invasive pneumococcal disease of vaccine-specific serotype)

Main results

There are no trials included in this review.

Authors' conclusions

As no trials were identified we cannot draw conclusions on the efficacy of routine pneumococcal immunisation in people with cystic fibrosis in reducing their morbidity or mortality. As many countries now include pneumococcal immunisation in their routine childhood vaccination schedule it is unlikely that future randomised controlled trials will be initiated. Rigorously conducted epidemiological studies may offer the opportunity to evaluate the efficacy of pneumococcal vaccination in reducing morbidity and mortality in people with cystic fibrosis.
