

primary studies - published RCT

# A randomized controlled trial of inhaled I-Arginine in patients with cystic fibrosis.

Code: PM23333044 Year: 2013 Date: 2013 Author: Grasemann H

## Study design (if review, criteria of inclusion for studies)

Double-blind, randomized, placebo-controlled crossover trial

## **Participants**

19 CF patients

#### Interventions

Twice daily inhalation of 500mg l-arginine for two weeks compared to inhalation of saline

#### **Outcome measures**

Safety and efficacy; exhaled NO, FEV(1), sputum concentrations of I-ornithine, the product of arginase activity and inflammatory markers in sputum

#### Main results

I-Arginine inhalation was well tolerated and resulted in a significant increase in exhaled NO. FEV(1) increased by an average of 56ml compared to -8ml after saline solution; but this difference did not reach statistical significance. Sputum concentrations of I-ornithine, the product of arginase activity, increased significantly while the I-ornithine derived polyamines did not. There was no change in inflammatory markers in sputum

## **Authors' conclusions**

Repeated inhalation of I-arginine in CF patients was safe and well tolerated. Inhaled I-arginine increased NO production without evidence for changes in airway inflammation.
