
primary studies - published RCT

Effects of probiotics on quality of life in children with cystic fibrosis; a randomized controlled trial.

Code: PM24910746

Year: 2013 **Date:** 2013

Author: Jafari SA

Study design (if review, criteria of inclusion for studies)

Prospective, randomized, controlled clinical trial

Participants

37 CF patients (2-12 years old)

Interventions

Patients were randomly divided into two groups. 20 patients of probiotic group took probiotics (2x10⁹CFU/d) for one month while 17 patients of control group took placebo capsules.

Outcome measures

Quality of life was determined using PedsQL4.0 questionnaire at the beginning, then three and six months after completing the treatment period. Rate of pulmonary exacerbation in probiotic group patients was also evaluated during three months after intervention and compared to the same three months of the previous year.

Main results

Significant improvement was observed in the mean total score of parent reported quality of life among probiotic group patients in comparison with placebo group at 3(rd) month (P=0.01), but this was not significant at 6(th) month of probiotic treatment. Rate of pulmonary exacerbation was significantly reduced among probiotic group (P

Authors' conclusions

Probiotics are considered as useful nutritional supplements on reducing number of pulmonary exacerbations and improving quality of life in patients with cystic fibrosis. Effects of probiotics seem to be temporary and probably continuous ingestion might have more stable improving effects on quality of life.
